33 **Findings**  
34  
35  
36

37 Thirty-seven candidate terpene synthase (TPS) genes were identified from a genome sequence of  
38 *Melaleuca alternifolia* (Australian tea tree), representing the six TPS subfamilies found in  
39 angiosperms. Compared to other well-characterised members of Myrtaceae, *M. alternifolia*  
40 possessed fewer TPS genes overall, but was proportionally over-represented in the TPS-b1, a  
41 subfamily of cyclic monoterpene synthases primarily involved in plant defence against  
42 pathogens. Proportionally high numbers of antimicrobial genes may have resulted from a  
43 lineage-specific expansion in *Melaleuca* in response to semi-aquatic origins.

4 **Abstract**  
5  
6

7  
8 Terpenes are a multifarious group of secondary compounds present throughout the living world  
9  
10 that function primarily in defence, or otherwise in regulating interactions between an organism  
11  
12 and its environment. Terpene synthases (TPS) are a mid-sized gene family, whose diversity and  
13  
14 makeup reflects a plant's ecological requirements and unique adaptive history. Here we  
15  
16 catalogue TPS in *Melaleuca alternifolia* and examine lineage-specific expansion in TPS relative  
17  
18 to other sequenced Myrtaceae. Overall, far fewer (37) putative TPS genes were identified in *M.*  
19  
20 *alternifolia* compared with *Eucalyptus grandis* (113) and *E. globulus* (106). The number of  
21  
22 genes in clade TPS-b1 (12), which produce cyclic monoterpenes, was proportionally larger in *M.*  
23  
24 *alternifolia* than in any other well-characterised plant, and relative to *E. grandis*, the  
25  
26 isoprene/ocimene-producing TPS-b2 clade in *M. alternifolia* tended to be proportionally smaller.  
27  
28 This suggested there may be lineage-specific subfamily change in *Melaleuca* relative to other  
29  
30 sequenced Myrtaceae, perhaps as a consequence of its semi-aquatic evolutionary history.

## 4 **Introduction**

5  
6

7 Terpenes are volatile, often aromatic hydrocarbon-based natural compounds produced by plants,  
8 fungi, bacteria and some insects, some of which play a role in primary metabolism but many of  
9 which are secondary metabolites (Chen et al. 2011). They are found in the essential oils, resins  
10 and other tissues of plants, and are believed to increase fitness in a variety of complex ways,  
11 including deterring or attracting insects and other herbivorous or pollinating organisms, resisting  
12 fungal or bacterial infection (phytoalexins), or by acting as allelochemicals (Külheim et al.  
13 2015). Isoprenes, for example, appear to alleviate heat stress (Behnke et al. 2007), perhaps by  
14 stabilising plant membranes or acting as antioxidants (Penuelas et al. 2005); ocimenes have been  
15 implicated in defence against insect herbivory (Navia-Giné et al. 2009; Shimoda et al. 2012).  
16 The biosynthetic pathways of terpenes are well-understood, and genes for terpene synthases  
17 (TPSs – enzymes that catalyse the terminal step of terpene structural modification from 5-carbon  
18 isoprene subunits) have already been well-described in plants such as *Arabidopsis* (Herde et al.  
19 2008) and *Eucalyptus* (Keszei et al. 2010).

36  
37  
38  
39  
40

41 TPS in plants typically exist as a mid-sized gene family (Chen et al. 2011) but can range in  
42 number from 1 in *Physcomitrella patens* (a bryophyte) to 113 in *Eucalyptus grandis*, with larger  
43 gene families tending to found in some woody perennials because of the key role of terpenes in  
44 defence over their long lifespans (Chen et al. 2011; Kulheim et al. 2015). Studies of the genome  
45 organisation of TPS show patterns of clustering into subfamilies at locations in the genome (e.g.  
46 Tuskan et al. 2006; Kulheim et al. 2015). **This mechanism of gene family evolution is consistent  
47 with rounds of gene duplication (Cannon et al. 2004), whereby sections of chromosomes are  
48 duplicated in uneven crossing over events or by the action of transposable elements. Gene

60  
61  
62  
63  
64  
65**

2  
3  
4 duplication is an important source of genetic variation, and duplications account for a large  
5  
6 proportion of genes in eukaryotic genomes (Pierce, 2012). When a single gene is duplicated and  
7  
8 inserted close to the original, it is termed a local or tandem duplication (TD; Cannon et al.,  
9  
10 2004).

11  
12  
13  
14 As with other gene families involved in adaptive responses, expansion or contraction in gene  
15  
16 family size for TPS is thought to occur in response to the nature of the stress (i.e. biotic or  
17  
18 abiotic) which appears to influence the magnitude of expansion (Hanada et al. 2008). Lespinet et  
19  
20 al. (2002) report that lineage-specific expansions of gene families resulting from retained TDs  
21  
22 are very frequently expansions of genes involved in stress response, but it is not clear which type  
23  
24 of stress has a stronger relationship with TDs. As an expansion in one orthologous group (OG) in  
25  
26 response to an adaptive force acting on one species is often mirrored by a contraction of the same  
27  
28 OG in a related but geographically separate species, lineage-specific gene family size variation  
29  
30 leaves different genomic signatures for different adaptive histories (Blanc and Wolfe 2004).

31  
32  
33  
34 A prominent feature of TPS enzymes is that they yield multiple products, with as many as 52  
35  
36 different terpenes being reported from one enzyme (Steele et al. 1998). The Myrtaceae family is  
37  
38 notable among the plant families of southern hemisphere origins for its number of essential oil-  
39  
40 rich taxa, and the abundance of TPS genes in some species (Külheim et al. 2015; Webb et al.  
41  
42 2014).

43  
44  
45  
46 Several eucalypts including *Eucalyptus* sp. and *Corymbia citriodora*, as well as *Melaleuca* sp.  
47  
48 are grown commercially for terpene-rich essential oil. Among the *Melaleuca*, *Melaleuca*  
49  
50 *alternifolia* (Maiden and Betche) Cheel is the most important for essential oil production because  
51  
52 of the proven antimicrobial activity of a major constituent, terpinen-4-ol (Baker 1999; Southwell  
53  
54 2003; Morcia et al. 2012). Because of its commercial importance, it is arguably the best-studied  
55  
56  
57

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 of any Myrtaceae in terms of terpene chemistry, biochemistry and genetics. Attempts have been  
5  
6 made to identify genes underlying biosynthesis of commercially important terpene components  
7  
8 and assign function (Shelton et al. 2002, 2004a, 2004b; Keszei et al. 2010b, unreviewed RIRDC  
9  
10 report; Webb et al. 2013; Webb et al. 2014) and regulation of oil yield (Webb et al. 2013), but as  
11  
12 yet only a single candidate TPS has been reported for this species (Shelton et al. 2004a; Sharkey  
13  
14 et al. 2005).  
15  
16  
17  
18  
19  
20

21 Here we catalogue the TPS genes identified in a draft genome sequence of *Melaleuca*  
22  
23 *alternifolia*. We conduct comparative analysis of the TPS gene family with other sequenced  
24  
25 Myrtaceae, including the reference Myrtaceae, *Eucalyptus grandis* (Grattapaglia et al. 2012;  
26  
27 Myburg et al. 2014; Kulheim et al. 2015). We find there are comparatively few TPS in *M.*  
28  
29 *alternifolia* relative to other woody perennials, but there is a tendency toward over-representation  
30  
31 of the TPS-b1 clade of cyclic monoterpene synthases, and under-representation of the TPS-b2  
32  
33 clade, a subfamily of isoprene/ocimene synthase gene class, relative to other sequenced  
34  
35 Myrtaceae.

## 4 **Materials and Methods**

5  
6

### 7 *Genome sequencing*

8  
9

10 A draft genomic sequence for the reference genotype SCU01 of *M. alternifolia* was generated  
11  
12 using short read Illumina sequence data (See [Online Resource 1](#) for details of Results and  
13  
14 Methodology). This individual has Chemotype 4 terpene chemistry (high 1,8-cineole and  
15  
16 intermediate terpinen-4-ol) and was clonally replicated and archived in a germplasm resource  
17  
18 collection located at the Lismore campus of SCU (Shepherd et al. 2015).  
19  
20  
21  
22  
23

24 Sequencing was performed on a HiSeq 2000 (Illumina) at the Australian Genome Research  
25  
26 Facility. In brief, a total of 100 Gb of high quality paired-end 100 bp long sequence reads were  
27  
28 generated by an Illumina HiSeq to give approximately 141 X genome coverage based on a  
29  
30 cytological estimate of 710 Mb (See [Online Resource 2](#)). Raw sequencing reads were trimmed to  
31  
32 remove low-quality bases and adaptor sequences. Reads in FASTQ format were first checked for  
33  
34 quality using FASTQC (Andrews 2015), followed by removal of adapter sequences, poly-N  
35  
36 stretches and low quality (Phred score < 20) reads using the BBDuck module of the BBDuck  
37  
38 software package (version 34\_90; <http://sourceforge.net/projects/bbmap>). A draft assembly of *M.*  
39  
40 *alternifolia* was constructed using the CLC de novo assembler (CLC Bio, Aarhus, Denmark).  
41  
42 The draft genome comprised a total of 221,396 contigs with total length of 356 Mb and an N50  
43  
44 of 8,778 bp.  
45  
46  
47  
48  
49  
50  
51  
52

53 Gene annotation with the Maker pipeline version v2.31.8 (Cantarel et al. 2008) produced  
54  
55 33,184 draft gene models with an annotation edit distance of >0.35. Analysis of single copy gene  
56  
57 coverage using the BUSCO method (Simão et al. 2015) predicted 90% of single copy genes  
58  
59  
60  
61  
62  
63  
64  
65

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 (80% complete, 10% fragmented) captured in this set of contigs (data not shown). To check  
5  
6 Maker's efficacy, tBLASTn was used against the *M. alternifolia* genome assembly to explore the  
7  
8 presence of TPS genes outside of Maker gene models (amino acid queries from Külheim et al.  
9  
10 2015. See [Online Resource 3](#)). Two query sequences (TPSb line 1 & TPSf line 2) returned no  
11  
12 hits. Hits to all other queries (116 in total) were associated (overlapping or contained within)  
13  
14 with gene models predicted by Maker (see [Online Resource 4](#) for tabulated results). This  
15  
16 suggests that the pipeline, which used protein sequence evidence from *E. grandis*, *C. citriodora*  
17  
18 and *Vitis* sp. to draw gene model predictions, is at least as effective as a straight homology  
19  
20 search, having search parameters relaxed enough to allow for some missing consensus sequences  
21  
22 and using multiple lines of evidence.  
23  
24  
25  
26  
27  
28  
29

### 30 *Mining the genome*

31  
32  
33  
34  
35 Methods in a 2015 study by Külheim et al. of TPS genes in *E. grandis* served as a template.  
36  
37 Using known conserved protein regions of 6 TPS subfamilies as BLAST queries (CoGeBLAST  
38  
39 and NCBI BLAST+, using default parameters), searches were performed on the *Melaleuca* v1  
40  
41 genome assembly.  
42  
43  
44  
45  
46

47 To establish whether the conserved domains (CDs) used for mining the *E. grandis*  
48  
49 genome were suitable for locating TPS genes and confidently assigning subfamilies in *M.*  
50  
51 *alternifolia*, one CD from each subfamily was BLASTed to both genomes, and the highest e-  
52  
53 values for each search recorded. E-values for both species were indeed comparable in  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 significance (for tabulated data see [Online Resource 5](#)), indicating that queries used to mine the  
5  
6 well-studied *E. grandis* reference Myrtaceae genome are applicable to *M. alternifolia*.  
7  
8  
9

10  
11 To gather a broad pool of candidates, a cutoff e-value of 1e-08 was used to select the highest  
12  
13 hits for each subfamily query (TPS-a, -b, -c, -e, -f and -g) to the *M. alternifolia* assembly. This  
14  
15 cutoff was established when it became apparent that any hits with e-values less significant than  
16  
17 1e-10 invariably appeared in multiple search results, indicating that the subfamily-specific  
18  
19 sensitivity of searches tapered off below that point. 1e-08 was chosen as a conservative value in  
20  
21 the event that some e-values of relevant gene models happened to fall below 1e-10.  
22  
23  
24  
25  
26  
27

28 The pool of candidate gene models returned by these searches was sorted by subfamily and  
29  
30 then structurally analysed using GEvo (<https://genomeevolution.org/coge/Gevo.pl>; Lyons &  
31  
32 Freeling 2008) to ascertain exon number (which varies depending upon subfamily; Külheim et  
33  
34 al. 2015), and FeatView (<https://genomeevolution.org/coge/FeatView.pl>) to ascertain number and  
35  
36 placement of stop codons. Models were given a ranking according to a modified version of  
37  
38 Külheim's system, which is as follows: 1 = full length, no premature stop codons; 2 = full length,  
39  
40 up to 2 stop codons; 3 = full length, no stop codon; 4 = pseudogenes, more than 2 stop codons; 5  
41  
42 = partial gene. (Ultimately, all classes of gene were included in the phylogeny, as incomplete  
43  
44 genes could have been truncated simply by being part of a very short contig.)  
45  
46  
47  
48  
49  
50  
51

52 Using ChloroP 1.1 (<http://www.cbs.dtu.dk/services/ChloroP/>) and PCLR release 0.9  
53  
54 (<http://www.andrewschein.com/cgi-bin/pclr/pclr.cgi>), models were analysed to detect the  
55  
56 presence of chloroplast transit peptide sequences (cTPs) (Emanuelsson et al. 1999). As all but the  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 sesquiterpenes (C15) are produced in the chloroplast (Külheim et al. 2015), most TPS genes  
5  
6 should contain a cTP.  
7  
8  
9

## 10 *Phylogeny*

11  
12  
13  
14  
15  
16 In order to replicate as closely as possible Külheim's phylogeny methods, a test run was  
17  
18 performed using only the 113 *E. grandis* TPS amino acid sequences published with the 2015  
19  
20 paper. Using PhyML 3.0 (<http://phylogeny.lirmm.fr>; Dereeper et al. 2008) a ClustalW alignment  
21  
22 was constructed from the 113 sequences. Gblocks curation was skipped, as the analysis returned  
23  
24 by a curated pipeline did not satisfactorily resolve some subfamilies (for example, TPS-e  
25  
26 appeared as a clade flanked either side by TPS-c genes).  
27  
28  
29  
30  
31  
32

33 As per Külheim et al., the Jones-Taylor-Thornton amino acid substitution model was used to  
34  
35 create a maximum-likelihood phylogenetic tree file (.tree) with 100 bootstrapped replicates, and  
36  
37 the resulting file was imported to FigTree v1.4.2 (<http://tree.bio.ed.ac.uk/software/figtree/>;  
38  
39 Rambaut 2014) for visualisation and editing. The tree ([Online Resource 6](#)) was manually rooted  
40  
41 from the node at which types I and III (i.e. subfamilies c, e, f and a, b, g) diverge.  
42  
43  
44  
45  
46

47 As the phylogenetic tree that resulted from using the above settings showed very high  
48  
49 structural similarity to that of Külheim et al. (2015), the same settings were applied using the set  
50  
51 of 113 *E. grandis* TPS genes plus the 37 *M. alternifolia* candidate gene models identified using  
52  
53 BLAST, as well as the coding sequence for the putative monoterpene synthase transcript  
54  
55 obtained by Shelton et al. (2004; GenBank accession AY279379.1) The alignment for this  
56  
57 phylogeny can be found in [Online Resource 7](#). A tree was constructed as outlined above; Figure  
58  
59

## 4 **Results**

### 5 6 7 *Putative TPS genes and subfamily proportions*

8  
9  
10  
11  
12 Thirty-seven candidate TPS genes with high similarity to conserved TPS regions were identified  
13  
14 in the *M. alternifolia* genome (Table 1; Figure 2; all gene models are listed in [Online Resource](#)  
15 [8](#); .fasta files of 37 amino acid sequences are attached as [Online Resource 9](#)).  
16  
17  
18  
19  
20  
21

22 Fourteen genes clustered with subfamily TPS-a, which produce sesquiterpenes (C15); twelve  
23  
24 with TPS-b1, which produce cyclic monoterpenes (C10, e.g. sabinene hydrate and 1,8-cineole);  
25  
26 two with TPS-b2, which produce isoprenes and ocimenes (C5, C10); one with TPS-c, which  
27  
28 produce diterpenes (C20); one with TPS-e, which produce mono-, sesqui- and diterpenes; three  
29  
30 with TPS-f, which also produce mono-, sesqui- and diterpenes; and four with TPS-g, which  
31  
32 predominantly produce acyclic mono-, sesqui- and diterpenes.  
33  
34  
35  
36  
37  
38

39 Of all well-studied plants represented in Table 1 and Figure 2, *M. alternifolia* has the highest  
40  
41 number of TPS-b1 genes as a proportion of the total number of TPS genes: 32.4%, compared  
42  
43 with *Populus trichocarpa*, the next-highest at 31.2%. TPS gene subfamily proportions do not  
44  
45 differ significantly between *M. alternifolia* and *E. grandis* ( $\chi^2= 1.74$ ;  $\chi_{crit}= 12.59$ ;  $p= 0.05$ ),  
46  
47 although tea tree has a proportionally larger set of TPS-b1 (cyclic monoterpene) genes and a  
48  
49 smaller set of TPS-b2 (isoprene/ocimene) genes. However, differences in subfamily proportions  
50  
51 between *M. alternifolia* and both *P. trichocarpa* (a well-characterised woody dicot) and *A.*

5  
6 respectively.  
7

### 8 9 10 11 *Transit peptides*

12  
13  
14  
15  
16 Only five *M. alternifolia* genes from TPS subfamilies -a (1 gene), -b1 (2), -b2 (1) and -g (1),  
17  
18 were predicted by ChloroP 1.1 to contain cTPs. For context, the 113 *E. grandis* genes from  
19  
20 Külheim et al. (2015) were run through ChloroP 1.1, which found six genes from subfamilies -a  
21  
22 (4), -b (1) and -e (1) with cTPs. (cTP-containing genes from both species are listed in [Online](#)  
23  
24 [Resource 10](#).) TPS-a genes with a predicted transit peptide were compared between *M.*  
25  
26 *alternifolia* and *E. grandis* (the sole predicted cTP-containing TPS-b gene from *E. grandis*,  
27  
28 Eucgr.K00875.1.v2.0, was found to be a very small, incomplete gene model, leaving only TPS-a  
29  
30 in common between the two species). Sequence identity between these TPS-a genes was between  
31  
32 70.1% (MelG016248 to Eucgr.H04978) and 82.3% (MelG016248 to Eucgr.F03396).  
33  
34  
35  
36  
37  
38  
39

40 Interestingly, results from analysis of the same 37 gene models using PCLR r0.9 returned the  
41  
42 same 5 models as predicted by ChloroP (see [Online Resource 11](#)), with no others predicted to  
43  
44 contain chloroplast transit peptides.  
45  
46  
47

48  
49  
50 Sequence identity between predicted cTP-containing TPS-a genes from both species did not  
51  
52 greatly exceed that between TPS-a genes not predicted to contain a cTP (70.1 - 82.3% for genes  
53  
54 with predicted cTPs, compared to 65.6 - 79.1% for those without, calculated by comparing 6  
55  
56 randomly-selected non-cTP *E. grandis* TPS-a genes with MelG016248, the only *M. alternifolia*  
57  
58 TPS-a gene predicted to contain a cTP). A BLAST search of the *Eucalyptus grandis* BRASUZ1  
59  
60  
61  
62

64  
65

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 (Phytozome unmasked v2) genome assembly using the amino acid sequence of MelG016248 did  
5  
6 return hits to 4 of 6 *E. grandis* predicted cTP-containing TPS-a genes (Eucgr.D01103,  
7  
8 Eucgr.E00419, Eucgr.F03396, and Eucgr.H04978). However, these hits ranged from HSP #88 to  
9  
10 #23, with many other genes returning higher scores, making it unlikely that these cTP-predicted  
11  
12 genes from both species are orthologues.  
13  
14

### 15 16 17 18 19 *Phylogeny*

20  
21  
22  
23 A foundation for comparative analysis was established by replicating the Külheim et al. 2015  
24  
25 phylogenetic tree for *E. grandis*. Our tree had a high degree of resemblance with that of Külheim  
26  
27 et al. 2015 (see [Online Resource 12](#) for .tree format file), with all subfamilies resolving into  
28  
29 clades of identical size and structure.  
30  
31

32  
33 Inclusion of the 37 *M. alternifolia* candidates, however, induced some repositioning of clades  
34  
35 (Figure 1; see [Online Resource 13](#) for .tree file). For example, resolution was lost in the splitting  
36  
37 within Type I subfamilies, with TPS-f appearing as a sister group to both -c and -e (in the *E.*  
38  
39 *grandis* phylogeny, -c split off first, followed by -e and then -f). Whereas, in the tree containing  
40  
41 only *E. grandis* genes, TPS-g was a sister to the greater -b group (bootstrap at g/b node = 0.53),  
42  
43 and the phylogeny that includes both species showed -g as a sister to -a. The inclusion of a set of  
44  
45 genes from a different (albeit closely-related) species therefore reduced certainty in the  
46  
47 branching order of TPS subfamily clades.  
48  
49  
50  
51

52  
53  
54  
55 The TPS-b1 gene MelG017535 showed very high divergence (as represented by branch  
56  
57 length in Figure 1) from the other genes in its clade. When an alignment and phylogeny were  
58  
59 produced using only the 37 *M. alternifolia* genes (tree not included in this report), MelG017535  
60  
61  
62  
63  
64  
65

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 showed a similarly high divergence from other TPS-b1 genes. The gene has 6 exons – 1 fewer  
5  
6  
7 than the usual 7 observed by Külheim et al.  
8  
9

10  
11 Finally, the *M. alternifolia* mRNA sequenced and classified as a putative monoterpene  
12  
13 synthase persistently clustered not with the TPS-b1 cyclic monoterpene subfamily, as originally  
14  
15 proposed by Shelton et al. (2004), but with the TPS-b2 isoprene/ocimene subfamily (ISPS). In  
16  
17 addition, this mRNA sequence had 100% sequence identity to one gene model in the *M.*  
18  
19

4 **Discussion**  
5  
6  
7

8  
9 *Putative TPS genes and subfamily proportions*  
10  
11  
12

13 Given the BUSCO gene coverage estimate of 90%, it is probable that there are slightly more (41)  
14 than 37 TPS genes in the *M. alternifolia* genome than inferred. Refinements to the genome  
15 assembly using data derived from further sequencing may bear this out. However, in sequencing  
16 a genome as highly heterozygous as *M. alternifolia* there is a chance that both alleles from one  
17 locus may be incorrectly assigned to different loci, which would appear to increase the number  
18 of paralogues on the assembly.  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29

30 From the much lower number of putative TPS genes found in *M. alternifolia* compared to *E.*  
31 *grandis* (37 versus 113), results imply that evolutionary forces have acted differentially upon the  
32 two lineages since they diverged. Although there are far fewer TPS genes in *M. alternifolia*  
33 overall, all subfamilies were nonetheless represented. TPS-c is conserved in land plants and is  
34 thought to represent the base of the TPS tree, originating as a diterpene synthase producing  
35 gibberellin (regulatory plant hormone) precursors (Yamaguchi 2008). TPS-e and -f – conserved  
36 in vascular plants – are also linked to hormone production, sharing a common progenitor gene  
37 coding for an ent-kaurene synthase, also a gibberellin precursor (Chen et al. 2011). In contrast,  
38 TPS-a, -b and -g are angiosperm-specific, and their products (mono-, sesqui- and diterpenes)  
39 have been characterised as playing ecological rather than primary metabolic or regulatory roles  
40 (Chen et al. 2011). A salient question is whether this low number of ‘ecological’ TPS genes in  
41

64  
65

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 *M. alternifolia* compared to *E. grandis* represents a reduction, or the retention of an ancestral  
5  
6  
7 state.

8  
9  
10  
11 Orthologous pairing has been observed in most of the TPS genes in *E. grandis*, with large  
12  
13  
14 genomic clusters consisting of both functional and pseudogenes (Külheim et al. 2015) pointing to  
15  
16 a proliferation of gene duplication events. Thornhill et al. (2015) report an estimated divergence  
17  
18 of the genera *Melaleuca* and *Eucalyptus* at ~68 million years ago, and that the closest sister tribe  
19  
20 to the Melaleucaceae, the monotypic Osbornieae (divergence ~56 million years ago), is the only  
21  
22 member of Myrtaceae to occur in a mangrove growth form and habitat. This suggests the  
23  
24 existence of a basal estuarine or riparian progenitor of these tribes between 68 and 56 million  
25  
26  
27 years ago.  
28  
29

30  
31  
32  
33 Sharkey et al. (2013) functionally characterised an isoprene synthase gene from *E.*  
34  
35 *globulus* (EglobTPS106; GenBank AB266390.1) that is almost identical (99.6%) to the *E.*  
36  
37 *grandis* gene EgranTPS084 (Eucgr.K00881; GenBank XM\_010037321), the single *E. grandis*  
38  
39 TPS-b2 gene that fulfils the criteria for isoprene synthases outlined in the 2013 Sharkey paper.  
40  
41 The remaining 8 TPS-b2 genes are putative ocimene synthases (or of unknown function). In *M.*  
42  
43 *alternifolia*, 2 putative TPS-b2 genes were identified by this study, one of which, MelG010433,  
44  
45 appears to code for the mRNA transcript described by Shelton et al. (2004) and functionally  
46  
47 characterised as an ISPS by Sharkey et al. (2005). The other *M. alternifolia* TPS-b2 gene,  
48  
49  
50 MelG013034, lacks the isoprene synthase-specific amino acids and may be considered a putative  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 ocimene synthase until it is functionally characterised. Thus, a breakdown of TPS-b2 for *E.*  
5  
6  
7 *grandis* is 1 isoprene, 8 ocimene, whereas for *M. alternifolia* it is 1 isoprene, 1 ocimene.  
8  
9

10  
11 Transcripts encoding ocimene synthases accumulate in leaves in response to insect  
12 herbivory (Navia-Giné et al. 2009). (E)- $\beta$ -ocimene appears to play a role in attracting the insect  
13 predators of herbivorous spider mites (Shimoda et al. 2012), which occur in Australia (Wilson et  
14 al. 1996). That *M. alternifolia* possesses only a single putative ocimene synthase gene, compared  
15 to *E. grandis*' 8, suggests that tea tree has either evolved other strategies to deter herbivores, or  
16 that pressures imposed by herbivory differ in magnitude or variety from those undergone by the  
17 eucalypts.  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27

28  
29  
30 In addition, the eucalypts appear to have a proportionally smaller TPS-b1 subfamily than  
31 *M. alternifolia*. TPS subfamily proportions observed in *Corymbia citriodora* subsp. *variegata*  
32 tend to mirror *Eucalyptus* sp. ratios: a proportionally larger TPS-b2 relative to TPS-b1 (cyclic  
33 monoterpene synthases). This suggests proportionally higher representation of the TPS-b2 may  
34 be a feature of the eucalypt group more broadly, reflecting either their higher degree of  
35 relatedness or their more similar ecological history.  
36  
37  
38  
39  
40  
41  
42  
43  
44

45  
46  
47 Conversely, the subfamily TPS-b1 is proportionally larger in *M. alternifolia* than in any  
48 representative plant (dicot, monocot or moss) in Figure 2, suggesting that duplicate retention or  
49 lineage-specific gene family expansion in this subfamily has been an important adaptation in tea  
50 tree. Cyclic monoterpenes have been shown to increase membrane permeability of fungal  
51 hyphae, effectively inhibiting growth of fungal plant pathogens (Tao et al. 2014). They have also  
52 been shown to inhibit the action of bacterial polygalacturonase enzymes, which phytopathogenic  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 bacteria use to break down the pectin of plant cell walls (Rasoul et al. 2012). Keszei et al.  
5  
6 (2010b, unreviewed RIRDC report) hypothesise that the ancestral form of the TPS-b1 enzyme  
7  
8 for both *Melaleuca* and *Eucalyptus* was one responsible for cineole biosynthesis. 1,8-cineole has  
9  
10 been shown to inhibit the growth of gram-positive and -negative bacteria, and yeasts (Silva et al.  
11  
12 2011).  
13  
14

15  
16  
17  
18  
19         Given the warm, subtropical habitat of tea tree's evolution, it is unsurprising that an  
20  
21 arsenal of antimicrobial secondary metabolites such as cyclic monoterpenes should have been  
22  
23 selected for. That at least two of the TPS-b1 genes appear to be the result of tandem duplication  
24  
25 raises the possibility that biotic stress may have stimulated the expansion of this TPS subfamily.  
26  
27 Barlow (1988) suggested that both *Melaleuca* and *Eucalyptus* may both have had their origins at  
28  
29 rainforest margins, from whence they differentiated – *Melaleuca* as a seasonally-drowned habitat  
30  
31 specialist, and *Eucalyptus* as a coloniser of low-nutrient, seasonally drier soils.  
32  
33  
34

### 35 36 37 38 *Transit peptides*

39  
40  
41  
42 The 113 *E. grandis* TPS genes identified by Külheim et al. (2015) are putatively functional based  
43  
44 on RNA expression data from seven tissue types. As listed in Table 1, *E. grandis* has at least 38  
45  
46 genes that do not encode cytosol-destined sesquiterpene synthases but do encode plastid-destined  
47  
48 TPS enzymes of other classes (from subfamilies -b1, -b2 and -c). Thus, we should expect at least  
49  
50 38 *E. grandis* genes with predicted cTPs. That ChloroP 1.1 predicted only 6 of these indicates  
51  
52 that such an analysis as applied to *M. alternifolia* may be erroneous. Therefore, the cTP data  
53  
54 returned by ChloroP 1.1 analysis should be regarded with caution. However, that both ChloroP  
55  
56 and PCLR predicted cTPs in the same 5 *M. alternifolia* gene models despite the programs'  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 differing systems of prediction (neural network versus principal component analysis,  
5  
6 respectively) adds another line of evidence to the putatively functional status of these 5 genes.  
7  
8  
9

10  
11 In a review of plastid transit peptides, Bruce (2001) noted that their “extreme diversity in  
12  
13 sequence and evolution” means that they are still poorly-characterised. It remains possible that  
14  
15 the ChloroP 1.1 and PCLR r0.9 software were unable to detect many of the cTPs of TPS genes in  
16  
17  
18 *M. alternifolia* and *E. grandis*.  
19  
20  
21

## 22 23 *Phylogeny*

24  
25  
26  
27  
28 Minor differences in some bootstrap values between the model phylogeny of Külheim et al.  
29  
30 (2015) and the one in this study may have been the result of unreleased manual adjustments to  
31  
32 the alignment performed by the authors of the 2015 study, or simply from slight variation in the  
33  
34 100 bootstrapped replicas used to construct the final consensus tree. Additionally, joint  
35  
36 confidence (i.e. overall confidence incorporating the bootstrap values of all nodes) in large trees  
37  
38 is inescapably low (Soltis and Soltis 2003). In any case, the phylogenetic trees produced in this  
39  
40 study possess nodes with bootstrap values of <80% in similar numbers to the trees of Külheim et  
41  
42 al., which illustrates fundamental uncertainties in the relationships between TPS subfamilies. It is  
43  
44 tempting to view a phylogeny with high bootstrap values as being directly reflective of the actual  
45  
46 relationships between loci. However, as Felsenstein (1985) notes, “Bootstrapping provides us  
47  
48 with a confidence interval within which is contained not the true phylogeny, but the phylogeny  
49  
50 that would be estimated upon repeated sampling of many characters from the underlying pool of  
51  
52 characters.” In other words, a bootstrap value indicates only that the analysis returned the same  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 result many times. From this we must be careful of confidently inferring actual evolutionary  
5  
6 relationships.

7  
8  
9  
10  
11 Confidence in the finer grouping of individual loci was much higher than for the broader  
12  
13 relationships between TPS clades, both in the phylogenetic tree produced by Külheim et al.  
14  
15 (2015) and the two trees produced for this study (with and without *M. alternifolia* genes).  
16  
17 However, the inferred relationships between TPS subfamilies mostly mirror those found by Chen  
18  
19 et al. (2011) in a phylogeny of putative full-length TPS genes from 7 sequenced plant genomes  
20  
21 and representative characterised gymnosperm TPS sequences. Slight differences lie in the  
22  
23 splitting of Type I (TPS-c, -e and -f) clade, and in the order of branching within Type III (TPS-a,  
24  
25 -b and -g). For the purposes of assigning TPS subfamilies to gene models, however, the  
26  
27 phylogeny produced in this study was deemed adequate.  
28  
29  
30  
31  
32  
33  
34

35 The 2011 study by Chen et al. characterised clades TPS-a, -b and -g as encoding enzymes  
36  
37 involved in ecological interactions rather than primary metabolism or hormonal regulation.  
38  
39 These three subfamilies, which show considerable divergence in sequence to the other TPS  
40  
41 clades, contain the highest number of putative TPS genes in *M. alternifolia* (14, 14 and 4 genes,  
42  
43 respectively) and together make up 32 of the 37 genes identified in this study. The remaining 5  
44  
45 genes from TPS-c, -e and dicot-specific TPS-f (1, 1 and 3 genes) are, based on the  
46  
47 characterisation of Chen et al., likely to encode enzymes that produce plant hormone precursors.  
48  
49

51  
52  
53  
54

55 The long branch of TPS-b1 gene MelG017535 suggests high divergence from the other genes  
56  
57 in that clade. However, its lack of a 7<sup>th</sup> exon compared to other TPS-b1 gene models could be  
58  
59 due to the inclusion of an intron, or fusion with another gene. If the striking difference in  
60

1 TPS genes in *M. alternifolia*: lineage-specific variation within Myrtaceae

2  
3  
4 sequence and single lost exon are not artefacts of sequencing or errors in gene model prediction,  
5  
6 this gene, once verified, warrants further investigation as a potential new subtype of TPS-b1.  
7  
8  
9

10  
11 Gene model MeIG010433, which is identical in sequence to the mRNA studied and classified  
12  
13 as a TPS-b1 monoterpene synthase gene by Shelton et al. (2004), showed a tendency to cluster  
14  
15 with TPS-b2 rather than TPS-b1 genes. This is supported by Sharkey et al. (2005), who  
16  
17 functionally characterised this transcript as an ISPS, and by Keszei et al. (2010), who also  
18  
19 concluded that the sequence codes for an ISPS in TPS-b2.

## 25 **Conclusion**

26  
27  
28 This study provides crucial baseline estimates for TPS gene numbers and subfamilies in *M.*  
29  
30 *alternifolia*. This information will be important in further elucidation of the tea tree's  
31  
32 evolutionary history, the broader study of gene family evolution, and in understanding in greater  
33  
34 detail the ecological functions of terpenes in the family Myrtaceae.

**Figure 1** Phylogeny of 37 *M. alternifolia* putative TPS genes with 113 *E. grandis* TPS genes from Külheim et al. (2015) and 1 *M. alternifolia* putative monoterpene synthase from Shelton et al. (2004). *M. alternifolia* genes are indicated by a black dot. Scale = average number of amino acid substitutions per branch (*JPEG produced using Figtree v1.4.2. And GIMP*)

**Figure 2** Proportion of TPS gene subfamilies found in 12 plant species as listed in Table 1. *M. alternifolia* contains the highest proportion of TPS-b1 genes. Gene proportions in *M. alternifolia* do not differ significantly from those in *E. grandis* ( $\chi^2= 1.74$ ;  $\chi_{crit}= 12.59$ ;  $p= 0.05$ ). (JPEG produced using LibreOffice Calc and GIMP).

**TERPENE SYNTHASE GENES IN MELALEUCA ALTERNIFOLIA: COMPARATIVE ANALYSIS OF  
LINEAGE-SPECIFIC SUBFAMILY VARIATION WITHIN MYRTACEAE**

Plant Systematics and Evolution

Authors: Jed Calvert\*, Abdul Baten\*, Jakob Butler<sup>‡</sup>, Bronwyn Barkla\* and Mervyn Shepherd<sup>\*^</sup>

\*Southern Cross Plant Science, Southern Cross University, Lismore Australia NSW 2480.

<sup>‡</sup>School of Biological Science, University of Tasmania, Hobart TAS 7005 Australia.

<sup>^</sup>Corresponding author: Dr Mervyn Shepherd, Southern Cross Plant Science, Southern Cross University, Lismore Australia NSW 2480. Email: mervyn.shepherd@scu.edu.au

**Phone: +61 2 66203412**

**For all tables in spreadsheet format, please refer to file *Calvert et al\_Tables.ods*. For Online Resources tables, please see folder *Calvert et al Online Resources*.**

**Table 1** Number of TPS genes in 12 plant species, broken down by TPS subfamily/class of terpene product. *M. alternifolia* has less than 1/2 of the number of TPS genes of three other Myrtaceae species, *E. grandis*, *E. globulus* and *C. citriodora* subsp. *variegata*, but still has representatives from all subfamilies found in Myrtaceae. Adapted from Chen et al. (2011) and Külheim et al. (2015). Methods for *C. citriodora* subsp. *variegata* data provided in Online Resource 14.

## Please read the important information on page 4 before you begin

This form should be used by authors to request any change in authorship. Please fully complete all sections. Use black ink and block capitals and provide each author's full name with the given name first followed by the family name.

### Section 1 Please provide the current title of manuscript

Manuscript ID no. PLSY-D-16-00354R1

Terpene synthase genes in *Melaleuca alternifolia*: comparative analysis of lineage-specific subfamily variation within Myrtaceae

### Section 2 Please provide the current authorship, in the order shown on your manuscript.

	First name(s)	Family name
1 <sup>st</sup> author	Jed	Calvert
2 <sup>nd</sup> author	Abdul	Baten
3 <sup>rd</sup> author	Jakob	Butler
4 <sup>th</sup> author	Mervyn	Shepherd
5 <sup>th</sup> author		
6 <sup>th</sup> author		
7 <sup>th</sup> author		

Please use an additional sheet if there are more than 7 authors.

### Section 3: Please

provide a justification for change. Please use this section to explain your reasons for changing the authorship of your manuscript. Please refer to the journal policy pages for more information about authorship. Please explain why omitted authors were not originally included on the submitted manuscript.

New data available on *Melaleuca alternifolia* genome size estimate. Although value in review paper was best available at the time, methodological refinement has provided improved more reliable and repeatable estimates tested on a wider range of ecotypes for the taxa. The proposed additional authors, ~~Tim Rhodes and~~ Bronwyn Barkla contributed to this work.

**Section 4 Proposed new authorship. Please provide your new authorship list in the order you would like it to appear on the manuscript.**

	First name(s)	Family name (this name will appear in full on the final publication and will be searchable on PubMed and similar databases)
1 <sup>st</sup> author	Jed	Calvert
2 <sup>nd</sup> author	Abdul	Baten
3 <sup>rd</sup> author	Jakob	Butler
4 <sup>th</sup> author	Bronwyn	Barkla
5 <sup>th</sup> author	Mervyn	Shepherd
6 <sup>th</sup> author		
7 <sup>th</sup> author		

Please use an additional sheet if there are more than 7 authors.

**Section 5 Author contribution, Acknowledgement and Disclosures. Please use this section to provide revised Author Contribution, Acknowledgement and/or Disclosures of your manuscript, ensuring you state what contribution any new authors made and, if appropriate acknowledge any contributors who have been removed as authors. Please ensure these are updated in your manuscript.**

**New Disclosures (potential conflicts of interest, funding, acknowledgements):**

The authors declare no conflict of interests

**New Author Contributions statement:**

Calvert - Carried out all primary analysis and interpretation and drafted and developed the manuscript  
 Baten - Prepared the platform resource of a Melaleuca genome sequence. Provided bioinformatic support and intellectual content, helping with design and choice of analysis.  
 Butler - Provided intellectual input into the development of the analytical approach and comparative analyses, aided in revising the manuscript and responding to reviewers comments

Shepherd - Conceived the project concept and primary design, contributed to the preparation of the original submission, responses to reviewers and revised version.

Barkla – Developed methodology, performed the flow cytometry estimation of genome size for Melaleuca and analysed data.

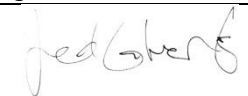

**New Acknowledgement Section:**

The authors wish to acknowledge the assistance of R. Wood, A. Kawamata, T. Rhodes and J. Bloomfield, for their help in the lab. Jed Calvert would also like to thank Shirali, for her constant support and supply of fresh perspectives. This work was supported by the Australian Research Council (grant number DP140102552).

State 'Not applicable' if there are no new authors.

**section 6 Declaration of agreement. All authors, unchanged, new and removed *must* sign this declaration.**

**\* please delete as appropriate. Delete all of the bold if you were on the original authorship list and are remaining as an author**

	First name	Family name		Signature	Affiliated institute	Date
1 <sup>st</sup> author	Jed	Calvert	I agree to the proposed new authorship shown in section 4		Southern Cross University	9 June 2017
2 <sup>nd</sup> author	Abdul	Baten	I agree to the proposed new authorship shown in section 4		Southern Cross University	9 June 2017
3 <sup>rd</sup> author	Jakob	Butler	I agree to the proposed new authorship shown in section 4		University of Tasmania	9 June 2017
4 <sup>th</sup> authors	Bronwyn	Barkla	I agree to the proposed new authorship shown in section 4 <b>and the addition of my name to the authorship list.</b>	 <hr/>	Southern Cross University	9 June 2017

5 <sup>th</sup> author	Mervyn	Shepherd	I agree to the proposed new authorship shown in section 4		Southern Cross University	13 June 2017
6 <sup>th</sup> author						

Please use an additional sheet if there are more than 7 authors. \* please delete as appropriate. Delete all of the bold if you were on the original authorship list and are remaining.

### Important information. Please read.

- Please return this form, fully completed, to the editorial office. We will consider the information you have provided to decide whether to approve the proposed change in authorship. We may choose to contact your institution for more information or undertake a further investigation, if appropriate, before making a final decision.
- Please note, we cannot investigate or mediate any authorship disputes. If you are unable to obtain agreement from all authors (including those who you wish to be removed) you must refer the matter to your institution(s) for investigation. Please inform us if you need to do this.
- If you are not able to return a fully completed form within **14 days** of the date that it was sent to the author requesting the change, we may have to reject your manuscript. We cannot publish manuscripts where authorship has not been agreed by all authors (including those who have been removed).
- Incomplete forms will be rejected.
