#### Abstract

The first arylpalladium(IV) complexes, [PdXMePhR(bpy)] (bpy = 2,2'-bipyridyl), have been isolated upon oxidative addition of methyl iodide or benzyl bromide to [PdMePh(bpy)]. These dialkyl(aryl)palladium(IV) complexes undergo reductive elimination in solution at *ca.* 0 °C:  $[PdBrMePh(CH,Ph)(bpy)]$  decomposes quantitatively into  $[PdBr(CH,Ph)(bpy)]$  and toluene whereas  $[PdIME_2Ph(bpy)]$  gives ethane and toluene in 4 : 1 ratio together with the corresponding complexes  $[PdIR(bpy)]$  ( $R = Me$  or Ph). The reaction of methyl iodide with [PdMePh(tmeda)] at 0 °C yields ethane and [PdIPh(tmeda)] without detection of a palladium(IV) intermediate. No reaction of [PdMePh(tmeda)] with benzyl bromide was observed. The first demonstration that organic groups can be transferred from palladium(IV) to palladium(II) is reported. The molecular structure of [PdMePh(bpy)] in the solid state has been determined.

Recently we reported the first examples of arylpalladium(II) nitrogen donor complexes in which the aryl group is not part of either an intramolecularly coordinating group or a metallacyclic system, *viz.*  [PdIPh(tmeda)] and [PdMePh(tmeda)] (1).<sup>1</sup> The remarkable stability of 1 and of its 2,2'-bipyridyl analogue [PdMePh(bpy)] (2) has enabled us to prepare novel arylpalladium(IV) complexes and to use these in a study of the selectivity of reductive elimination from dialkyl(aryl)palladium(IV) compounds. Moreover, we have observed the first example of alkyl halide transfer from palladium(lV) to palladium(I1).

Yellow [PdMePh(bpy)] (2) was obtained from the reaction of [pdMePh(tmeda)] (1) with bpy in benzene and was recrystallized from acetone/pentane. The molecular structure? of 2 (figure I) shows a square planar coordinated palladium with the methyl and phenyl group *cis* to each other and the phenyl group oriented approximately normal to the coordination *Fig. I.* ORTEP drawing (50% probability level) of the plane (the angle between the least-squares planes of molecular structure of [PdMePh(bpy)] (2). Selected the phenyl ring  $[C11...C16]$  and of the coordination bond lengths  $(\AA)$  and angles  $(0)$ : Pd-C17 2.020(5), Pdplane [Cll, CI7, NI, N2] is 78.68(19)°). The bond Cll 1.985(3), Pd-Nl 2.117(3), Pd-N2 2.138(3), Nllengths and bond angles have values similar to those  $Pd-N2 77.21(10)$ , C11-Pd-C17 85.69(19), N1-Pd-C11-<br>observed earlier in related complexes.<sup>1</sup> C12 98.7(3). observed earlier in related complexes.<sup>1</sup>

C5 ani C15  $C16$ C6)  $C11$  $C14$ CЯ  $C13$  $Pd$ C12 N2  $C10$ C17

<sup>1</sup>H NMR studies of the reactions of MeI and PhCH<sub>2</sub>Br with 1 and 2 were conducted by adding an excess of the alkyl halide to a solution of each complex in  $(CD_3)_2CO$  at -60 °C, followed by warming until reaction occurred. Reaction of 1 with MeI at  $0^{\circ}$ C gives [PdIPh(tmeda)] and ethane only, without a detectable pailadium(IV) intermediate (equation I).

#### $PdMePh(tmeda) + Mel \longrightarrow PdIPh(tmeda) + MeMe$  (1) 1

However, 2 reacts at  $0^{\circ}$ C to give spectra consistent with the formation of two isomeric forms of  $[PdIME_2Ph(bpy)]$  (3) (figure 2). The isomers are unstable at 0 °C and undergo reductive elimination to

Fig. 2. Isomers of  $[PdIME_2Ph(bpy)]$  (3), present in *ca*.  $1:1$  ratio in CDCl<sub>3</sub>.

form ethane (80%), toluene (20%), and  $[PdIR(bpy)]^{3,4}$ (equation 2) and were not observed in pure form under these conditions. The selectivity in reductive elimination from [PdIMe<sub>2</sub>Ph(bpy)] (equation 2), and

$$
PdMePh(bpy) + Mel \longrightarrow PdIME2Ph(bpy) \longrightarrow 2
$$
  
2  
3  
0.8[PdIPh(bpy) + MeMe]  
0.2[PdIME(bpy) + MePh] (2)

presumably also from [PdIMe<sub>2</sub>Ph(tmeda)] (equation 1), is consistent with the reported preference for ethane elimination from a range of PdIVXMe<sub>2</sub>R complexes where  $R \neq \text{aryl}, e.g.$  [PdBrMe<sub>2</sub>(CH<sub>2</sub>Ph)(L<sub>2</sub>)].<sup>5,6a</sup> Surprisingly, benzyl bromide does not react with 1 even at 50°C (the decomposition temperature of the latter complex in acetone) although 2 readily forms [PdBrMePh(CH<sub>2</sub>Ph)(bpy)] (4) (equation 3) at  $0^{\circ}$ C. Complex 4 undergoes a relatively slow reductive elimination at  $0<sup>o</sup>C$ , with exclusive coupling of phenyl and methyl groups (equation 3).4

$$
PdMePh(bpy) + PhCH2Br \longrightarrow PdBrMe(CH2Ph)Ph(bpy)
$$
  
2  
 
$$
\longrightarrow PdBr(CH2Ph)(bpy) + MePh
$$
 (3)

The inability of  $PhCH<sub>2</sub>Br$  to react with 1 may be ascribed to steric effects. Such effects have been found to be very important in  $S_N^2$  reactions of platinum(II) complexes, *e.g,* [PtMez(phen)] reacts *ca.* 1,000 times slower with EtI than with MeI.7 Although the two dimethylamino groups in [PdMePh(tmeda)] are in the nucleophile instead of in the electrophile, their size may well be a dominant factor in determining the relative reactivities of 1 and 2. In addition, the dimethylamino groups appear to encourage dissociation of iodide from [PdIMe<sub>3</sub>(tmeda)],<sup>8</sup> and

halide dissociation is implicated as the first step in reductive eliminations from  $Pd^{IV}Me<sub>3</sub>$  complexes.<sup>6b,8</sup>

The palladium(IV) complexes  $[PdIME_2Ph(bpy)]$  (3) and  $[PdBrMePh(CH<sub>2</sub>Ph)(bpy)]$  (4) were isolated as white solids on reaction of [PdMePh(bpy)] with excess alkyl halide at 0 °C in acetone, followed by addition of pentane (4) or cooling to  $-60$  °C and addition of pentane  $(3)$ .<sup>10</sup> In the <sup>1</sup>H spectrum (CDCl<sub>3</sub>) of 3 the presence of two isomers is indicated by three wellresolved bpy-H6 resonances at 9.10 ppm (d, 2H, 3b), 8.98 ppm (d, IH, 3a) and 8.76 ppm (d, IH, 3a). We believe that the H6 resonance of 3a next to the phenyl group lies at high field owing to the proximity of this H6 to the phenyl ring which is forced to lie approximately normal to the bpy plane *(cf.* figure I). The relative intensities of the H6 resonances indicate that the isomers 3a and 3 b occur in *ca.* I : I ratio. This result is consistent with the three methyl signals found at  $2.31$   $(3b)$ ,  $2.30$   $(3a)$ and 1.70 (3a) ppm with intensity ratio  $2:1:1$ corresponding to three Pd<sup>IV</sup>-bound methyls in different environments. A comparison with spectra of PdIMe<sub>2</sub>R(bpy) ( $R = Me<sup>9b</sup> CH<sub>2</sub>CH=CH<sub>2</sub>11$ ) indicates that the two low-field resonances correspond to methyl groups *trans* to bpy and the upfield resonance to a methyl group *trans* to iodine.

The <sup>1</sup>H NMR spectrum (CDCl<sub>3</sub>) of 4 shows unique PdMe, PdPh, and PdCH<sub>2</sub>Ph environments, and two pyridine-ring environments. The *PdMe* resonance, at 2.39 ppm, occurs downfield from that of the methyl groups in  $[PdBrMe<sub>2</sub>(CH<sub>2</sub>Ph)(bpy)]$  (1.98 ppm). Because the latter complex has both methyl groups trans to bpy, $5<sup>b</sup>$  and resonances for PdMe groups trans to a halogen are generally upfield from those trans to nitrogen donors,  $8,9$  it is reasonable to assume that compound 4 has either structure 4a or 4b (figure 3).

 $Fig.3.$  Possible isomers of  $[PdBrMe(CH,Ph)Ph(bpy)]$  $(4).$ 

Since  $[PdMe<sub>2</sub>(bpy)]$  forms more stable palladium(IV) compounds than does [PdMePh(bpy)], the reactivity of [PdMe<sub>2</sub>(bpy)] toward [PdBrMePh(CH<sub>2</sub>Ph)(bpy)] (4) was investigated. <sup>1</sup>H NMR studies in  $(CD_3)_2CO$  at 0 °C showed selective benzyl-transfer as in equation 4.

$$
PdBrMe(CH_2Ph)Ph(bpy) + PdMe_2(bpy) \longrightarrow
$$

$$
\longrightarrow \text{PdMePh(bpy)} + \text{PdBrMe}_2(\text{CH}_2\text{Ph})(\text{bpy}) \tag{4}
$$

This reaction probably follows the same mechanism as was proposed by Canty and Puddephatt for the alkyl halide transfer from  $PdBrMe<sub>2</sub>(CH<sub>2</sub>Ph)(phen)$ ] to [ptMez(phen)].6a

The isolation of arylpalladium(IV) complexes indicates that organopalladium(IV) chemistry now extends beyond the initially reported alkyl and benzyl complexes. The observation of selectivity in reductive elimination (equations 1-3) and in the transfer of groups from palladium(IV) to palladium(II) (equation 4) may be important in the further development of this new oxidation state in organic synthesis and catalysis.
