Abstract

An air- and moisture-tolerant alternate synthetic pathway to the preparation of a cationic chelated bis(NHC) methylpalladium(II) complex, $[\{(MesIm)_2CH_2\}Pd(Me)(NCMe)][PF_6]$, is described. The pathway involves the isolation of a bis(NHC) Ag(I) complex, $[\{(MesIm)_2CH_2\}_2Ag_2][PF_6]_2$, via metallation of the corresponding diimidazolium salt with Ag_2O followed by carbene transfer to [(COD)PdBrMe]. This new method avoids a previously reported unstable intermediate that displayed rapid decomposition at room temperature, attaining the targeted cationic methylpalladium(II) complex in high yield. CO/ethylene copolymerisation catalysis trials are reported showing solvent dependent catalyst lifetime and copolymer yields. Preliminary ethylene insertion studies are also outlined revealing possible pathways leading towards catalyst deactivation.

Introduction

Transition metal–alkyl/aryl complexes serve as an important class of catalysts for homogeneous alkene oligomerisation/polymerisation reactions.[1,2,3] It has also been established that the generation of a vacant coordination site adjacent the alkyl/aryl group allows for rapid migration processes leading to significantly more active catalyst species when compared to their coordinatively saturated analogues.[4]

Group 10-based catalysts are especially relevant due to their functional group tolerance enabling copolymerisation of polar monomers where traditional Ziegler-Natta type catalysts are incompatible.[5] The formation and catalytic utility of palladium(II) alkyl complexes featuring various supporting ligands such as monodentate NHCs,[6] chelated diimine,[7] bisphosphine[8] and even hybrid P/O,[9] P/N,[10] and NHC/O[11] mixed donor ligands are well documented all displaying varying degrees of catalytic competence.

Interestingly, initial studies investigating alkyl migration processes performed with monodentate NHC methylpalladium(II) complexes only resulted in limited catalytic utility due to high susceptibility of CO, Me and/or H insertion into the Pd–C (NHC) bond leading to catalyst deactivation resulting from the formation of 2-acyl/alkylimidazolium salts via reductive elimination.[6] It was not until Herrmann et al.[12] demonstrated the viability of dicationic chelated bis(NHC) palladium(II) complexes in CO/ethylene copolymerisation did the potential advantages of chelated bis(NHC) ligands in this class of catalysis become evident. The advantage of chelated bis(NHC) ligands was also observed by Green et al. noting that thermal decomposition of related Ni(II) complexes did not proceed via reductive elimination.[13] However, despite extensive reports dedicated to the preparation and catalytic applications of chelated bis(NHC) palladium(II) complexes, methods for the generation of their metal-alkyl derivatives remain limited to strategies that necessitate the formation of highly air, moisture and temperature sensitive free carbene intermediates.[14] The first report for the preparation of a cationic chelated bis(NHC) methylpalladium(II) complex was by Slaughter and co-workers employing the free carbene strategy which involved the isolation of an unstable intermediate palladium(II) methyl iodide complex. They also
52　demonstrated facile CO insertion into the Pd–Me bond giving promise for activity in
53　CO/ethylene copolymerisation catalysis.[15] Detailed carbonylation kinetic studies were
54　also conducted.

55　　Additionally, presumably owing to limited synthetic strategies available in accessing these
56　complexes, to the best of our knowledge, detailed polymerisation-type catalysis studies
57　featuring this important class of cationic chelated bis(NHC) methylpalladium(II) complexes
58　are conspicuously absent in the literature. Hence, we herein report an alternate synthetic
59　pathway to access a previously reported cationic chelated bis(NHC) methylpalladium(II)
60　complex, along with its utility in CO/ethylene copolymerisation and preliminary studies in
61　ethylene oligomerisation.

62

63　**Results and Discussions**
64　**Synthesis of [{(MesIm)$_2$CH$_2$}Pd(Me)(NCMe)][PF$_6$]**
65　Slaughter *et al.*[15] first synthesised the cationic chelated bis(NHC) methylpalladium(II)
66　acetonitrile complex [{(MesIm)$_2$CH$_2$}Pd(Me)(NCMe)][BF$_4$], **D** *via* Scheme 1. This
67　involved air- and moisture-sensitive free carbene generation and the isolation of the
68　chelated bis(NHC) methylpalladium iodide complex [{(MesIm)$_2$CH$_2$}Pd(Me)(I)], **C**,
69　which displayed rapid decomposition at room temperature. Therefore, we sought to
70　explore alternate synthetic routes to obtain **D** or an analogue thereof.

R = 2,4,6-trimethylphenyl

71　Scheme 1. Literature[15] reported synthetic route to cationic chelating bis(NHC)
72　palladium methyl acetonitrile complex [{(MesIm)$_2$CH$_2$}Pd(Me)(NCMe)][BF$_4$], **D**.

73

74　Initial attempts were aimed at starting from a pre-formed chelated bis(NHC) palladium
75　dihalide complex [{(MesIm)$_2$CH$_2$}PdX$_2$] (X = I, Br or Cl) which can be easily accessed
76　in good yield *via in situ* deprotonation of the corresponding diimidazolium dihalide salt
77　with Pd(OAc)$_2$.[12] Furthermore, treatment with methylating agents to form a complex
78　analogous to **C**, followed by Ag(I) salt halide abstraction would in principle afford **D**.
79　SnMe$_4$ and MeLi were tested as potential methylating agents (Scheme 2).

R = 2,4,6-trimethylphenyl

80 Scheme 2. Proposed methylation reactions with pre-formed $[\{(MesIm)_2CH_2\}PdBr_2]$
81 with $SnMe_4$ and MeLi.
82
83 Attempted synthesis according to Scheme 2 only resulted in intractable metal complex
84 decomposition mixtures, which may be due to innate instability of the corresponding
85 palladium(II) methyl halide complexes or possible ligand decomposition as noted by
86 the formation of large amounts of palladium black. This led to the use of the more
87 readily accessible [(COD)PdBrMe] (COD = 1,5-cyclooctadiene) complex with the
88 already intact Pd–Me bond. The labile COD ligand can be easily replaced with the target
89 bis(NHC) ligand of interest. Synthesis of [(COD)PdBrMe] followed a modified
90 literature procedure involving the methylation of [(COD)PdBr_2] with tetramethyltin and
91 was structurally authenticated with single crystal X-ray diffraction analysis (see ESI).
92 Ligand substitution was attempted *via* Ag(I) carbene transmetallation. Consistent with
93 literature precedent of NHC silver complexes forming a diverse range of structures and
94 aggregates,[16,17] initial reactions between Ag_2O and diimidazolium dihalide salts resulted
95 in inseparable product mixtures from which reaction stoichiometries were difficult to
96 control, as the bis(NHC) disilver complexes had complex Ag_xBr_y counteranions that
97 varied with recrystallisation conditions. Recent bis(NHC) palladium catalysed C–H
98 activation studies performed by Strassner *et al.*[18] also attempted to exploit the Ag(I)
99 NHC transmetallation route to generate chelating bis(NHC) complexes but only resulted
100 in dinuclear methylpalladium(II) complexes with bridging bis(NHC) ligands despite
101 dilution and substituent modifications. A new approach was pursued by substitution of
102 coordinating bromide counteranions with the non-coordinating $[PF_6]^-$ anion.
103

R = 2,4,6-trimethylphenyl

104 Scheme 3. Synthesis of **1** *via* Ag_2O deprotonation and metallation of diimidazolium
105 salt **A** followed by halide abstraction and anion substitution.

106

107 Our new approach involved firstly stirring the diimidazolium dibromide, **A** with Ag_2O
108 in dichloromethane with the exclusion of light for 24 hours, followed by solvent removal
109 under vacuum. The resulting light brown solid was re-dissolved in acetonitrile and 2
110 equivalents of $AgPF_6$ was added (Scheme 3). This was stirred for 1 hour at room
111 temperature with the exclusion of light, filtered to remove AgBr salts, and the solvent
112 removed under vacuum to afford a colourless solid, $[\{(MesIm)_2CH_2\}_2Ag_2][PF_6]_2$ **1** in
113 40% yield. ^{1}H NMR spectroscopic studies supported the formation of the bis(NHC)
114 Ag(I) complex with the absence of imidazolium NC*H*N signals. The presence of three
115 methyl signals at 2.44, 1.61 and 1.28 ppm indicated restricted rotation of the mesityl
116 rings in solution at room temperature. Distinct signals at 7.27 and 6.53 ppm supports a
117 twisted boat conformation of the bis(NHC) silver macrocyclic ring, resulting in an *AB*
118 spin system of the methylene *CH₂* hydrogen atoms. Single crystals were grown by
119 vapour diffusion of diethyl ether into a saturated acetonitrile solution. X-ray crystal
120 structure analysis was consistent with the NMR spectroscopic data discussed above, and
121 the structure of **1** (Figure 1) is analogous to the previously reported $[BF_4]^-$ analogue.[17]
122 Ag–C (carbene) bond lengths were comparable at 2.072(6) – 2.084(6) Å with a weak
123 Ag–Ag interaction at 3.111(9) Å.

124

125 Figure 1. Crystal structure of dicationic bridging bis(NHC) Ag(I) complex
126 $[\{(MesIm)_2CH_2\}_2Ag_2][PF_6]_2$ **1**. Thermal ellipsoids are shown at the 50% probability
127 level. All hydrogen atoms and $[PF_6]^-$ anions are removed for clarity. Selected bond
128 lengths (Å) and angles (°): Ag1···Ag2 3.1113(9), Ag1–C1,C27 2.084(6), 2.081(6), Ag2–
129 C5,C31 2.072(6), 2.074(6), C1–Ag1–C27 172.6(2), C5–Ag2–C31 170.4(2), Ag1–C1–
130 N1,N2 128.4(5), 127.5(5), Ag1–C27–N5,N6 122.5(4), 133.4(5), Ag2–C5–N3,N4
131 133.7(5), 122.8(4), Ag2–C31–N7,N8 127.2(5), 128.2(5).

132

133 Synthesis of the target cationic palladium(II) methyl acetonitrile adduct (PF_6^- analogue
134 of **D**) proceeded in one-step without the need for dry solvents or an inert atmosphere,
135 also circumventing the previously reported unstable intermediate **C**.[15] Transmetallation
136 reactions of **1** with 2 equivalents of [(COD)PdBrMe] were conducted in acetonitrile
137 with the exclusion of light for 1 hour at room temperature, affording an off-white
138 solution with grey AgBr precipitate (Scheme 4). This was removed *via* filtration and the
139 solvent removed *in vacuo*, affording an off-white solid. Purification by recrystallisation
140 produced colourless rods of $[\{(MesIm)_2CH_2\}Pd(Me)(NCMe)][PF_6]$ **2** in 80% yield,
141 suitable for X-ray crystal structure determination. ^{1}H NMR spectroscopic analysis

142 showed NHC ligand resonances similar to that reported for Slaughter's analogous [BF$_4$]$^-$
143 complex.[15] Characteristic resonances at -0.56 and 1.86 ppm were indicative of Pd–CH_3
144 and Pd–NCCH_3 hydrogen atoms, respectively, and the absence of COD resonances
145 supported successful ligand substitution. Elemental composition was also confirmed *via*
146 satisfactory microanalysis. X-ray crystallographic studies revealed the bonding
147 connectivity of the bis(NHC) ligands to be chelated in a mononuclear palladium
148 complex (Figure 2). Pd–C (carbene, *trans* to acetonitrile), Pd–C (carbene, *trans* to
149 methyl), Pd–N (acetonitrile) and Pd–C (methyl) bond lengths were as expected at
150 1.986(5), 2.092(5), 2.056(5) and 2.072(6) Å, respectively, as was the bis(NHC) chelate
151 bite angle at 86.02(2) °. The longer Pd–C (carbene) bond *trans* to the CH$_3$ ligand is
152 consistent with the fact that CH$_3$ is a strong σ-donor. Such *trans* influence of a CH$_3$
153 ligand is also seen in other cationic palladium methyl complexes.[15]
154

R = 2,4,6-trimethylphenyl

155
156 Scheme 4. Synthesis of [{(MesIm)$_2$CH$_2$}Pd(Me)(NCMe)][PF$_6$], **2** *via* air and moisture
157 tolerant transmetallation reaction of **1** with (COD)PdBrMe.

158 Figure 2. Crystal structure of cationic chelated bis(NHC) palladium methyl acetonitrile
159 complex [{(MesIm)$_2$CH$_2$}Pd(Me)(NCMe)][PF$_6$], **2**. Thermal ellipsoids are shown at the
160 50% probability level. All hydrogen atoms and [PF$_6$]$^-$ anions are removed for clarity.
161 Selected bond lengths (Å) and angles (°): Pd1–C1,C5 2.092(5), 1.986(5), Pd1–N5
162 2.056(5), Pd1–C26 2.072(6). C5–Pd1–C1 86.02(2), N5–Pd1–C26 85.29(2), C1–Pd1–

164 134.81(4), 121.76(5), Pd1–C5–N3,N4 124.36(4), 122.07(5).
165

CO/Ethylene Copolymerisation and Ethylene Homooligomerisation

Kinetic experiments performed by Slaughter showed facile CO insertion into the Pd–CH$_3$ bond of **D** resulting in an equilibrium between a Pd-acyl complex and a Pd–CO methyl complex, of which the Pd–CO complex was structurally characterised.[15] However, to the best of our knowledge, subsequent reactions of this cationic chelated bis(NHC) methylpalladium(II) complex and its acyl derivative with ethylene remain absent in the literature. Our initial investigations focussed on the catalytic performance of **2** in the copolymerisation of carbon monoxide and ethylene given the established reactivity of **2** with CO. A summary of the catalytic trials is given in Table 1.

Table 1. CO/ethylene copolymerisation catalysed by **2**[a].

Entry	Complex	Solvent	Temperature (°C)	Time (h)	Copolymer Yield (g copolymer/ mmol Pd)
1	2	MeOH	R.T.	2	0.418
2	2	MeOH	70	2	1.37
3[b]	2	MeOH	70	2	2.70
4	2	CH$_2$Cl$_2$	70	2	7.70
5	2	CH$_2$Cl$_2$	70	24	8.43

[a] Conditions: 20 bar CO, 20 bar CH$_2$CH$_2$, 2.89 x 10^{-2} mmol **2**, volume = 50 mL.
[b] Temperature of the reaction was slowly increased from 50 °C to 70 °C over the course of 1 hr and maintained at 70 °C for the remaining catalysis experiment.

All copolymerisation trials resulted in low copolymer yields. However, in comparison with previous reports featuring dicationic bis(NHC) palladium(II) complexes,[19] in our hands complex **2** remains more active. Reaction solutions were also analysed by GC-MS and no evidence for short chain CO/ethylene co-oligomers was found consistent with previous studies.[19] Increasing the temperature from room temperature to 70 °C improved catalyst performance *ca.* threefold. As seen in Table 1, the reaction solvent also seemed to play an important role in catalyst activity as reflected by copolymer yields. Reactions performed in MeOH resulted in comparatively less copolymer than those conducted in CH$_2$Cl$_2$. The role of MeOH as a possible contributor to the transformation of **2** into a catalytically inactive complex is presumably linked to previous theoretical[20] and experimental[21,22] reports on σ-bond metathesis reactions involving alcohols and Pd–Me complexes. MeOH coordination followed by elimination of methane would result in the formation of a Pd–OMe species that can undergo β–hydrogen elimination generating a Pd–H complex. Although, in theory, this would be another initiation pathway for CO/ethylene copolymerisation, however, our previous reports[23] have suggested that bis(NHC) Pd(II)–H complexes are likely to undergo reduction to Pd(I) species that are yet to show activity in this class of catalysis.

Methanol solvent non-innocence warranted the need for a change in catalysis solvent, in this case from MeOH to CH$_2$Cl$_2$. Employing CH$_2$Cl$_2$ nearly tripled the copolymer yield presumably due to extended catalyst life. However, copolymer yield did not increase greatly with increased reaction time (entry 5), suggesting that long-term catalyst stability is still an issue with this system. This may be due to instability of the intermediate catalytic species resulting from chain termination processes, which could also generate a Pd–H species. Furthermore, in the absence of monomer substrates, **2** does decompose both in solution and solid state at room temperature over a period of 6 hours in solution and 2 days in solid state affording palladium black, likely *via* Pd–CH$_3$ reductive elimination as is commonly seen for NHC Pd–alkyl complexes.[6]

Slaughter and co-workers performed kinetic investigations of carbonylation reactions relevant to CO/ethylene copolymerisation and were able to structurally authenticate a cationic methylpalladium CO species. *In situ* detection of a Pd–acyl species resulting from CO insertion into the Pd–CH$_3$ bond was also achieved.[15] However, to the best of our knowledge, what remains absent is the investigation of ethylene insertion into the Pd–CH$_3$ or Pd–acyl bond for this class of chelating bis(NHC) ligands.

214   ^{1}H NMR spectroscopic studies investigating ethylene insertion processes were
215   conducted in CD_2Cl_2 under 1 atmosphere of ethylene at room temperature. A sharp
216   singlet at 5.36 ppm confirmed the presence of ethylene in solution; the sample was not
217   replenished with ethylene after initial charging (Figure 3). Ethylene insertion into the
218   Pd–Me bond proved to be quite rapid, as introduction of ethylene immediately resulted
219   in a reduction of signal intensity for the Pd–CH_3 hydrogen atoms at -0.53 ppm and
220   formation of oligomeric products of ethylene with multiplets at *ca.* 1.63, 1.65, 4.85, 5.15
221   and 5.90 ppm.

222   Figure 3. Room temperature ^{1}H NMR spectra of complex **2** in CD_2Cl_2 and upon
223   immediate addition of 1 atmosphere of C_2H_4.
224
225   Concomitant with the consumption of ethylene was the formation of Pd black and also
226   what is likely to be ligand decomposition as seen in the subsequent complexity of the
227   ^{1}H NMR spectrum. In order to better identify the ethylene oligomer products seen in the
228   ^{1}H NMR spectrum, **2** was placed in a high-pressure (10 bar) Young's NMR tube and
229   charged with 10 bar of ethylene. The sample was kept at 0 °C for 24 hours after which
230   saw complete consumption of ethylene and catalyst decomposition as indicated by the
231   formation of Pd black and absence of coordinated ligand resonances in the NMR
232   spectrum.
233   The formation of propene is suggested by multiplets at 5.95 and 1.66 ppm, indicating
234   propene CH and CH_3 protons respectively, along with CH_2 hydrogen resonances at 4.97
235   and 5.04 ppm. 1-butene was also indicated by CH_2 and CH_3 signals at 2.11 and 1.90
236   ppm, respectively, along with other signals indicative of unsaturated oligomeric
237   products. Analysis by GC-MS confirmed the formation of propene, 1-butene, *cis*- and
238   *trans*-2-butene, along with small amounts of C_6 alkenes from ethylene trimerisation or
239   ethylene/butene codimerisation. **2** showed a total TON of 120 with *ca.* a 9:1 C_4/C_6
240   ethylene oligomer product ratio. The proposed mechanism of ethylene dimerisation
241   catalysed by **2** is shown in Scheme 5, and is analogous to that established previously.[24,25]

242 Propene results from initial insertion into the Pd-methyl bond (chain initiation), the
243 butenes are subsequently formed catalytically by ethylene insertion reactions into a Pd–
244 H species followed by β–hydrogen elimination.
245

246 Scheme 5. Proposed reaction mechanism showing the formation of ethylene oligomers.
247
248 In both atmospheric and high-pressure experiments, upon introduction of ethylene to a
249 CD$_2$Cl$_2$ solution of **2**, a number of other spectroscopic changes can be seen which are
250 indicative of structural transformations occurring at the Pd centre. Concomitant with a
251 decrease in the Pd–CH_3 signal intensity at -0.53 ppm is the appearance of a broad singlet
252 at 0.42 ppm. This signal disappeared when all ethylene was consumed, suggesting it to
253 possibly be associated with a transient Pd–alkyl complex(es) undergoing rapid β–H
254 elimination and insertion processes. Another characteristic change in the NMR
255 spectrum can be seen at 6.34 ppm, which corresponds to the CH_2 methylene bridge
256 hydrogen atoms of the ligand. Upon reaction with ethylene an adjacent singlet at 6.33
257 ppm appears which increases in size with time until the singlet at 6.34 ppm disappears.
258 This suggests the complete transformation of **2** into a secondary species. Attempted
259 isolation of olefin insertion Pd complexes proved difficult, nor could Pd–H resonances
260 be observed in low temperature ^{1}H NMR spectroscopic experiments which may have
261 resulted from Pd–alkyl complexes bearing β–hydrogens prone to reductive
262 decomposition processes, and hence was not further pursued.

263 **Conclusion**

264 In conclusion, an improved synthetic route for the preparation of cationic chelated
265 bis(NHC) palladium(II) methyl complexes has been developed *via* a Ag(I) carbene
266 transmetallation process with [(COD)PdBrMe]. This method proved to be high yielding
267 and tolerant to both air and moisture affording pure complex **2** avoiding the putative
268 unstable and prone to decomposition intermediate chelated bis(NHC) PdXMe complex
269 and access to highly sensitive free carbene species which may have played a role in the
270 lack of detailed studies present in the literature featuring complexes analogous to **2**.
271 Although not presented in this work, our newly developed method has the potential to
272 be applied to a wider range of bis(NHC) ligands and late transition metal centres
273 relevant to homogeneous polymerisation catalysis.
274 Preliminary CO/ethylene copolymerisation and ethylene homooligomerisation
275 studies were also conducted in methanol and CH$_2$Cl$_2$. Copolymer yields seemed to be
276 solvent dependent with catalysis conducted in CH$_2$Cl$_2$ affording the highest yields in

| 277 | this study. Reactions in methanol produced considerably lower copolymer yields |
| 278 | suggestive of some degree of solvent interaction with the active catalytic species. |

Complex **2** was also shown to be active in ethylene homooligerisation producing 1-, 2-, *cis*- and *trans*-butenes, along with traces of C_6 alkenes rationalised by literature reported reaction mechanisms. However, catalyst performance in both copolymerisation and homooligomerisation over a range of conditions proved poor, catalyst complex stability remains an obstacle for this system.

Further work regarding reaction mechanisms of methanol solvent non-innocence with regards to catalyst **2** is topical for this class of chelated bis(NHC) palladium(II) complexes. Understanding bis(NHC) ligand lability and solvent-dependent complex reactivity is paramount towards revealing catalyst stability and developing improved catalyst design.

Experimental

General Considerations

All syntheses of imidazolium salts and anion exchange reactions of metal complexes were carried out in air. Some analyses were performed in a dry glove box (Innovative Technologies) under a nitrogen atmosphere. Anhydrous dimethylsulfoxide and methanol were purchased from Sigma-Aldrich and stored over 3 Å molecular sieves. CP grade ethylene (BOC gases) were purified by passage through a column of activated 3 Å molecular sieves and alumina, and CP grade carbon monoxide (BOC gases) was used as received. 1,1'-dimesityl-3,3'-methylenediimidazolium dibromide,[12] [(COD)PdBrMe][26] and [{(MesIm)$_2$CH$_2$}PdBr$_2$][12] were prepared according to literature methods. All other reagents were purchased from Sigma-Aldrich and used as received. NMR spectra were recorded on a Varian Mercury Plus 300 spectrometer (^{1}H, 299.9 MHz; ^{13}C{^{1}H}, 75.4 MHz) in CDCl$_3$ or DMSO-d_6 at 20 °C unless otherwise noted. ^{1}H NMR and ^{13}C NMR spectra were referenced to the residual ^{1}H resonance of the solvent residual peaks, while ^{13}C NMR spectra were referenced to the deuterated ^{13}C resonance. *J* values are given in Hz. Elemental analyses were carried by the Central Science Laboratory at the University of Tasmania using a Carlo Erba EA1108 Elemental Analyser or Medac Ltd, UK. GC-MS analyses were carried by the Central Science Laboratory at the University of Tasmania using a Varian 3800 GC coupled to a Varian 1200 triple quadrupole MS. Electronic Supplementary Information (ESI) available: CCDC references numbers 1863141, 1863142 and 186143

Syntheses

[{(MesIm)$_2$CH$_2$}$_2$Ag$_2$][PF$_6$]$_2$. (1) Ag$_2$O (0.67 g, 1.36 mmol) and 1,1'-dimesityl-3,3'-methylenediimidazolium dibromide (0.32 g, 1.22 mmol) were stirred in 25 mL CH$_2$Cl$_2$ in exclusion of light at room temperature overnight. The mixture had all solvent removed *in vacuo* affording a grey solid that was redissolved in 25 mL CH$_3$CN and stirred with AgPF$_6$ (0.68 g, 2.70 mmol) for 2 hours at room temperature. This resulted in a clear solution with a grey precipitate that was removed *via* Celite filtration and all solvent removed *in vacuo*. The off-white solid was recrystallised *via* layering of Et$_2$O over a saturated CH$_3$CN solution affording colourless crystals of **1** (0.63 g, 0.49 mmol, 40%). ^{1}H NMR (DMSO-d_6): δ 8.08 (s, 4H, *H*C=CH), 7.49 (s, 4H, *H*C=CH), 7.27 (d, 2H, *J* = 13.6 Hz, NC*H$_2$*N), 7.09 (s, 4H, *aryl-H*), 6.97 (s, 4H, *aryl-H*), 6.53 (d, 2H, *J* = 13.6 Hz, NC*H$_2$*N), 2.44 (s, 12H, *p-* or *m-aryl-CH$_3$*), 1.61 (s, 12H, *p-* or *m-aryl-CH$_3$*), 1.28 (s, 12H, *p-* or *m-aryl-CH$_3$*). ^{13}C NMR (DMSO-d_6): δ 182.4 (*carbene-C*), 180.5 (*carbene-C*), 139.2 (*aryl-C*), 135.4 (*aryl-C*), 129.6 (*aryl-C*), 125.1 (*aryl-C*), 122.8 (*aryl-C*), 65.4 (N*C*H$_2$N), 64.0 (N*C*H$_2$N), 21.2 (*C*H$_3$), 17.2 (*C*H$_3$), 16.9 (*C*H$_3$). Found: C, 46.87; N, 8.48; H, 4.85. Calc. for C$_{50}$H$_{56}$N$_8$Ag$_2$P$_2$F$_{12}$: C, 47.11; N, 8.79; H, 4.43.

[{(MesIm)$_2$CH$_2$}Pd(Me)(NCMe)][PF$_6$]. (2) 1 (0.25 g, 0.199 mmol) and [(COD)PdBrMe] (0.12 g, 0.399 mmol) were dissolved and stirred in 25 mL CH$_3$CN at room temperature with the exclusion of light for 1 hour affording a colourless solution with grey precipitate. This was filtered through Celite and the filtrate had all solvent removed *in vacuo*. The resulting white solid was re-crystallised *via* vapour diffusion of Et$_2$O into a saturated CH$_2$Cl$_2$ solution affording colourless rods of **2** (0.21 g, 0.196 mmol, 80%). mp. 230.1 °C (dec). ^{1}H NMR (CD$_2$Cl$_2$): δ 7.60 (dd, 2H, J = 4.8 Hz, 1.5 Hz, H*C*=C*H*), 7.02 (s, 2H, *aryl-H*), 6.95 (s, 2H, *aryl-H*), 6.89 (dd, 2H, $^3J_{HH}$ = 4.5Hz, 1.8 Hz, H*C*=C*H*), 6.31 (s, 2H, NC*H$_2$*N), 2.35 (s, 3H, *p-aryl-CH$_3$*), 2.33 (s, 3H, *p-aryl-CH$_3$*), 2.09 (s, 6H, *o-aryl-CH$_3$*), 2.03 (s, 6H, *o-aryl-CH$_3$*), 1.85 (s, 3H, C*H$_3$*CN), -0.56 (s, 3H, Pd-C*H$_3$*). ^{13}C NMR (DMSO-*d$_6$*): δ 182.5 (*carbene-C*), 165.7 (*carbene-C*), 138.8 (*aryl-C*), 138.7 (*aryl-C*), 136.1 (*aryl-C*), 135.9 (*aryl-C*), 135.3 (*aryl-C*), 134.8 (*aryl-C*), 129.1 (*aryl-C*), 124.5 (*aryl-C*), 123.5 (*aryl-C*), 122.4 (*aryl-C*), 121.6 (N*C*CH$_3$), 65.4 (*CH$_2$*), 21.0 (*CH$_3$*), 20.9 (*CH$_3$*), 18.7 (*CH$_3$*), 18.3 (*CH$_3$*), 1.6 (NC*C*H$_3$), -8.2 (Pd-*C*H$_3$). Found: C, 46.83; N, 9.34; H, 4.90. Calc. for C$_{28}$H$_{34}$N$_5$PdPF$_6$·0.5CH$_2$Cl$_2$: C, 46.61; N, 9.54; H, 4.80.

Ethylene/carbon monoxide copolymerisation trials

[{(MesIm)$_2$CH$_2$}Pd(Me)(NCMe)][PF$_6$]. 2 (0.020 g, 0.028 mmol) was dissolved in methanol or CH$_2$Cl$_2$ (40 mL) under argon atmosphere and transferred to a 0.3 L stainless steel Parr 5500 Compact Mini Reactor also under an argon atmosphere. The autoclave was charged in turn with 20 bar of ethene and 20 bar of carbon monoxide, and stirred for two hours at the appropriate temperature. The autoclave was then chilled with ice before venting to ensure no loss of volatile (co)oligomeric products. The reaction mixture contained a grey solid which was collected *via* filtration. The reaction solutions were analysed by GS-MS for oligomeric product.

X-Ray Crystallography

Data for **2** was collected at -173 °C on crystals mounted on a Hampton Scientific cryoloop at the MX1 beamline of the Australian Synchrotron,[27] while data for **1** were collected at -173 °C on crystals mounted on a Hampton Scientific cryoloop on Bruker QUEST. The structures were solved by direct methods with SHELXT-2014, refined using full-matrix least-squares routines against F^2 with SHELXT-2014,[26] and visualised using OLEX2.[27] All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were placed in calculated positions and refined using a riding model with fixed C–H distances of 0.95 Å (*sp*^{2}CH), 1.00 Å (*sp*^{3}CH), 0.99 Å (CH$_2$), 0.98 Å (CH$_3$). The thermal parameters of all hydrogen atoms were estimated as U_{iso}(H) = 1.2U_{eq}(C) except for CH$_3$ where U_{iso}(H) = 1.5U_{eq}(C). Disorder in solvent molecules were modelled using atom splitting in OLEX2. A summary of crystallographic data for [(COD)PdBrMe], **1** and **2** is given below.

Crystal data for [(COD)PdBrMe]: C$_9$H$_{15}$BrPd, M = 309.52, orthorhombic, a = 6.9300(4), b = 10.970(6), c = 12.770(7) Å, U = 970.8(3) Å^3, T = 100 K, space group P2$_1$2$_1$2$_1$ (no 19), Z = 4, 22596 reflections measured, 2154 unique (R_{int} = 0.0433), 2144 > 4σ(F), R = 0.0222 (observed), R_w = 0.0569 (all data). Crystal data for **1**: C$_{50}$H$_{56}$N$_8$Ag$_2$P$_2$F$_{12}$·(C$_4$H$_{10}$O)(CH$_3$CN), M = 1389.88, triclinic, a = 13.8979(4), b = 22.6233(7), c = 23.4706(7) Å, α= 62.8440(10), β = 85.7340(10), γ = 73.2260(10) °, U = 6272.4(3) Å^3, T = 100 K, space group P-1 (no. 2), Z = 4, 227109 reflections measured, 26226 unique (R_{int} = 0.0472), 21905 > 4σ(F), R = 0.0327 (observed), R_w = 0.0721 (all data). Crystal data for **2**: C$_{28}$H$_{34}$N$_4$PdPF$_6$, M = 691.97, monoclinic, a = 12.680(3), b = 21.929(4), c = 12.918(3) Å, β= 117.45(3) °, U = 3187.5(13) Å^3, T = 100 K, space group $P2_1/n$ (no. 14), Z = 4, 60816 reflections measured, 8476 unique (R_{int} = 0.0621), 6742 > 4σ(F), R = 0.0639 (observed), R_w = 0.1878 (all data).
